The “pinhole” camera model

Projection (Source: Wikipedia)

Model

The “pinhole” camera (French: sténopé):

- ▶ Ideal model with an aperture reduced to a single point.
- ▶ No account for blur of out of focus objects, nor for the lens geometric distortion.

Central projection in camera coordinate frame

- ▶ Rays from C are the same: $\vec{Cm} = \lambda \vec{CM}$
- ▶ In the camera coordinate frame $CXYZ$:

$$\begin{pmatrix} x \\ y \\ f \end{pmatrix} = \lambda \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}$$

- ▶ Thus $\lambda = f/Z$ and

$$\begin{pmatrix} x \\ y \end{pmatrix} = f \begin{pmatrix} X/Z \\ Y/Z \end{pmatrix}$$

- ▶ In pixel coordinates:

$$\begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} \alpha x + c_x \\ \alpha y + c_y \end{pmatrix} = \begin{pmatrix} (\alpha f)X/Z + c_x \\ (\alpha f)Y/Z + c_y \end{pmatrix}$$

- ▶ αf : focal length *in pixels*, (c_x, c_y) : position of principal point P in pixels.

Conclusion

Practical session/Home assignment

Projective plane

- ▶ We identify two points of \mathbb{R}^3 on the same ray from the origin through the equivalence relation:

$$\mathcal{R} : \mathbf{x} \mathcal{R} \mathbf{y} \Leftrightarrow \exists \lambda \neq 0 : \mathbf{x} = \lambda \mathbf{y}$$

- ▶ Projective plane: $\mathbb{P}^2 = (\mathbb{R}^3 \setminus O) / \mathcal{R}$
- ▶ Point $(x \ y \ z) = (x/z \ y/z \ 1)$ if $z \neq 0$.
- ▶ The point $(x/\epsilon \ y/\epsilon \ 1) = (x \ y \ \epsilon)$ is a point “far away” in the direction of the line of slope y/x . The limit value $(x \ y \ 0)$ is the infinite point in this direction.
- ▶ Given a plane of \mathbb{R}^3 through O , its equation is $aX + bY + cZ = 0$. It corresponds to a line in \mathbb{P}^2 represented in homogeneous coordinates by $(a \ b \ c)$. Its equation is:

$$(a \ b \ c) (X \ Y \ Z)^\top = 0.$$

Projective plane

- ▶ Line through points \mathbf{x}_1 and \mathbf{x}_2 :

$$\ell = \mathbf{x}_1 \times \mathbf{x}_2 \text{ since } (\mathbf{x}_1 \times \mathbf{x}_2)^\top \mathbf{x}_i = |\mathbf{x}_1 \quad \mathbf{x}_2 \quad \mathbf{x}_i| = 0$$

- ▶ Intersection of two lines ℓ_1 and ℓ_2 :

$$\mathbf{x} = \ell_1 \times \ell_2 \text{ since } \ell_i^\top (\ell_1 \times \ell_2) = |\ell_i \quad \ell_1 \quad \ell_2| = 0$$

- ▶ Line at infinity:

$$\ell_\infty = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \text{ since } \ell_\infty^\top \begin{pmatrix} x \\ y \\ 0 \end{pmatrix} = 0$$

- ▶ Intersection of two “parallel” lines:

$$\begin{pmatrix} a \\ b \\ c_1 \end{pmatrix} \times \begin{pmatrix} a \\ b \\ c_2 \end{pmatrix} = (c_2 - c_1) \begin{pmatrix} b \\ -a \\ 0 \end{pmatrix} \in \ell_\infty$$

Calibration matrix

- ▶ Let us get back to the projection equation:

$$\begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} fX/Z + c_x \\ fY/Z + c_y \end{pmatrix} = \frac{1}{Z} \begin{pmatrix} fX + c_x Z \\ fY + c_y Z \end{pmatrix}$$

(replacing αf by f)

- ▶ We rewrite:

$$Z \begin{pmatrix} u \\ v \\ 1 \end{pmatrix} := \mathbf{x} = \begin{pmatrix} f & c_x \\ & f & c_y \\ & & 1 \end{pmatrix} \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}$$

- ▶ The 3D point being expressed in another orthonormal coordinate frame:

$$\mathbf{x} = \begin{pmatrix} f & c_x \\ & f & c_y \\ & & 1 \end{pmatrix} (R \quad T) \begin{pmatrix} X \\ Y \\ Z \\ 1 \end{pmatrix}$$

Calibration matrix

- ▶ The (internal) **calibration matrix** (3×3) is:

$$K = \begin{pmatrix} f & & c_x \\ & f & c_y \\ & & 1 \end{pmatrix}$$

- ▶ The **projection matrix** (3×4) is:

$$P = K \begin{pmatrix} R & T \end{pmatrix}$$

- ▶ If pixels are trapezoids, we can generalize K :

$$K = \begin{pmatrix} f_x & s & c_x \\ & f_y & c_y \\ & & 1 \end{pmatrix} \text{ (with } s = -f_x \cotan \theta \text{)}$$

Theorem

Let P be a 3×4 matrix whose left 3×3 sub-matrix is invertible. There is a unique decomposition $P = K \begin{pmatrix} R & T \end{pmatrix}$.

Proof: Gram-Schmidt on rows of left sub-matrix of P starting from last row (RQ decomposition), then $T = K^{-1}P_4$.

Projective plane (perspective effect)

- ▶ Lines parallel in space project to a line bundle (set of lines parallel or concurrent). Let \mathbf{d} be a fixed direction vector:

$$K(\mathbf{X} + \lambda \mathbf{d}) = K\mathbf{X} + \lambda K\mathbf{d}$$

$$\ell_{\mathbf{X}} = (K\mathbf{X}) \times (K\mathbf{d})$$

$$\forall \mathbf{X}, \ell_{\mathbf{X}}^{\top} \mathbf{v} = 0 \quad \text{for } \mathbf{v} := K\mathbf{d}$$

- ▶ \mathbf{v} is the vanishing point of lines of direction \mathbf{d} .
- ▶ If $\mathbf{v}_1 = K\mathbf{d}_1$ and $\mathbf{v}_2 = K\mathbf{d}_2$ are vp of “horizontal” lines, another set of horizontal lines has direction $\alpha \mathbf{d}_1 + \beta \mathbf{d}_2$, hence its vp $\alpha \mathbf{v}_1 + \beta \mathbf{v}_2$, which belongs to line $\mathbf{v}_1 \times \mathbf{v}_2$, the “horizon”.

Homographies

Let us see what happens when we take two pictures in the following particular cases:

1. **Rotation around the optical center** (and maybe change of internal parameters).

$$\mathbf{x}' = K'RK^{-1}\mathbf{x} := H\mathbf{x}$$

2. **The world is flat.** We observe the plane $Z = 0$:

$$\mathbf{x}' = K \begin{pmatrix} R_1 & R_2 & R_3 & T \end{pmatrix} \begin{pmatrix} X \\ Y \\ 0 \\ 1 \end{pmatrix} = K \begin{pmatrix} R_1 & R_2 & T \end{pmatrix} \mathbf{x} := H\mathbf{x}$$

In both cases, we deal with a 3×3 invertible matrix H , a homography.

Property: a homography preserves alignment. If $\mathbf{x}_1, \mathbf{x}_2, \mathbf{x}_3$ are aligned, then

$$|H\mathbf{x}_1 \quad H\mathbf{x}_2 \quad H\mathbf{x}_3| = |H||\mathbf{x}_1 \quad \mathbf{x}_2 \quad \mathbf{x}_3| = 0$$

Homographies

Type	Matrix	Invariants
Rigid (Rot.+Trans.)	$H = \begin{pmatrix} c & -s & t_x \\ s & c & t_y \\ 0 & 0 & 1 \end{pmatrix} \quad (c^2 + s^2 = 1)$	angles, distances
Similarity	$H = \begin{pmatrix} c & -s & t_x \\ s & c & t_y \\ 0 & 0 & 1 \end{pmatrix}$	angles, ratio of distances
Affine	$H = \begin{pmatrix} a & b & t_x \\ c & d & t_y \\ 0 & 0 & 1 \end{pmatrix}$	parallelism
Homography	H invertible	cross- ratio of 4 aligned points

Given 4 aligned points A, B, C, D , their cross-ratio is:

$$(A, B; C, D) = \frac{AC}{BC} : \frac{AD}{BD}$$

Homographies: estimation from point correspondences

Theorem Let $e_1, \dots, e_{d+1}, f_1, \dots, f_{d+1} \in \mathbb{R}^d$ such that any d vectors e_i (resp. f_i) are linearly independent. Then there are (up to scale) a unique isomorphism H and a unique set of scalars $\lambda_i \neq 0$ so that $\forall i, H e_i = \lambda_i f_i$.

1. **Analysis:** writing $e_{d+1} = \sum_{i=1}^d \mu_i e_i$ and $f_{d+1} = \sum_{i=1}^d \nu_i f_i$,

$$\sum_{i=1}^d \nu_i \lambda_{d+1} f_i = \lambda_{d+1} f_{d+1} = H e_{d+1} = \sum_{i=1}^d \mu_i \lambda_i f_i$$

so that $\forall i = 1, \dots, d : \mu_i \lambda_i = \nu_i \lambda_{d+1}$.

2. $\forall i, \mu_i \neq 0$ and $\nu_i \neq 0$, since $\mu_i = 0 \Rightarrow \{e_j\}_{j \neq i}$ are linearly dependent.
3. Therefore we get $\lambda_i = \frac{\nu_i}{\mu_i} \lambda_{d+1}$.
4. **Synthesis:** fix $\lambda_{d+1} = 1$ and $\forall i : \lambda_i = \frac{\nu_i}{\mu_i} \neq 0$.
5. There is a unique H mapping basis $\{e_i\}_{i=1, \dots, d}$ to basis $\{\lambda_i f_i\}_{i=1, \dots, d}$

Application: given $n + 2$ pairs $(\mathbf{x}_i, \mathbf{x}'_i) \in \mathbb{P}^n$, there is a unique homography mapping \mathbf{x}_i to \mathbf{x}'_i .

Optimization techniques

Conclusion

Practical session/Home assignment

Panorama construction

- ▶ We stitch together images by correcting homographies. This assumes that the scene is flat or that we are rotating the camera.
- ▶ Homography estimation:

$$\lambda \mathbf{x}' = H\mathbf{x} \Rightarrow \mathbf{x}' \times (H\mathbf{x}) = 0,$$

which amounts to 2 independent linear equations per correspondence $(\mathbf{x}, \mathbf{x}')$.

- ▶ 4 correspondences are enough to estimate H (but more can be used to estimate through mean squares minimization).

Panorama from 14 photos

Algebraic error minimization

- ▶ $\mathbf{x}_i' \times (H\mathbf{x}_i) = 0$ is a system of three linear equations in H .
- ▶ We gather the unknown coefficients of H in a vector of 9 rows

$$\mathbf{h} = (H_{11} \quad H_{12} \quad \dots \quad H_{33})^\top$$

- ▶ We write the equations as $A_i \mathbf{h} = 0$ with

$$A_i = \begin{pmatrix} x_i & y_i & 1 & 0 & 0 & 0 & -x_i'x_i & -x_i'y_i & -x_i' \\ 0 & 0 & 0 & x_i & y_i & 1 & -y_i'x_i & -y_i'y_i & -y_i' \\ -x_iy_i' & -y_iy_i' & -y_i' & x_i'x_i & x_i'y_i & x_i' & 0 & 0 & 0 \end{pmatrix}$$

- ▶ We can discard the third line and stack the different A_i in A .
- ▶ \mathbf{h} is a vector of the kernel of A (8×9 matrix)
- ▶ We can also suppose $H_{3,3} = h_9 = 1$ and solve

$$A_{:,1:8} \mathbf{h}_{1:8} = -A_{:,9}$$

Geometric error

- ▶ When we have more than 4 correspondences, we minimize the algebraic error

$$\epsilon = \sum_i \|\mathbf{x}'_i \times (H\mathbf{x}_i)\|^2,$$

but it has no geometric meaning.

- ▶ A more significant error is geometric:

- ▶ Either $d'^2 = d(\mathbf{x}', H\mathbf{x})^2$ (transfer error) or $d^2 + d'^2 = d(\mathbf{x}, H^{-1}\mathbf{x}')^2 + d(\mathbf{x}', H\mathbf{x})^2$ (Symmetric transfer error)

Gold standard error/Maximum likelihood estimator

- ▶ Actually, we can consider \mathbf{x} and \mathbf{x}' as noisy observations of ground truth positions $\hat{\mathbf{x}}$ and $\hat{\mathbf{x}}' = H\hat{\mathbf{x}}$.

$$\epsilon(H, \hat{\mathbf{x}}) = d(\mathbf{x}, \hat{\mathbf{x}})^2 + d(\mathbf{x}', H\hat{\mathbf{x}})^2$$

- ▶ **Problem:** this has a lot of parameters: $H, \{\hat{\mathbf{x}}_i\}_{i=1\dots n}$

Sampson error

- ▶ A method that linearizes the dependency on $\hat{\mathbf{x}}$ in the gold standard error so as to eliminate these unknowns.

$$0 = \epsilon(H, \hat{\mathbf{x}}) = \epsilon(H, \mathbf{x}) + J(\hat{\mathbf{x}} - \mathbf{x}) \text{ with } J = \frac{\partial \epsilon}{\partial \mathbf{x}}(H, \mathbf{x})$$

- ▶ Find $\hat{\mathbf{x}}$ minimizing $\|\mathbf{x} - \hat{\mathbf{x}}\|^2$ subject to $J(\mathbf{x} - \hat{\mathbf{x}}) = \epsilon$
- ▶ **Solution:** $\mathbf{x} - \hat{\mathbf{x}} = J^\top (JJ^\top)^{-1} \epsilon$ and thus:

$$\|\mathbf{x} - \hat{\mathbf{x}}\|^2 = \epsilon^\top (JJ^\top)^{-1} \epsilon \quad (1)$$

- ▶ Here, $\epsilon_i = A_i h = \mathbf{x}'_i \times (H\mathbf{x}_i)$ is a 3-vector.
- ▶ For each i , there are 4 variables $(\mathbf{x}_i, \mathbf{x}'_i)$, so J is 3×4 .
- ▶ This is almost the algebraic error $\epsilon^\top \epsilon$ but with adapted scalar product.
- ▶ The resolution, through iterative method, must be initialized with the algebraic minimization.

Applying homography to image

Two methods:

1. **push** pixels to transformed image and round to the nearest pixel center.
2. **pull** pixels from original image by interpolation.

Conclusion

Practical session/Home assignment

Camera calibration by resection

[R.Y. Tsai, *An efficient and accurate camera calibration technique for 3D machine vision*, CVPR'86] We estimate the camera internal parameters from a known rig, composed of 3D points whose coordinates are known.

- ▶ We have points \mathbf{X}_i and their projection \mathbf{x}_i in an image.
- ▶ In homogeneous coordinates: $\mathbf{x}_i = P\mathbf{X}_i$ or the 3 equations (but only 2 of them are independent)

$$\mathbf{x}_i \times (P\mathbf{X}_i) = 0$$

- ▶ Linear system in unknown P . There are 12 parameters in P , we need 6 points in general (actually only 5.5).
- ▶ Decomposition of P allows finding K .

Restriction: The 6 points cannot be on a plane, otherwise we have a degenerate situation; in that case, 4 points define the homography and the two extra points yield no additional constraint.

Calibration with planar rig

[Z. Zhang *A flexible new technique for camera calibration* 2000]

- ▶ **Problem:** One picture is not enough to find K .
- ▶ **Solution:** Several snapshots are used.
- ▶ For each one, we determine the homography H between the rig and the image.
- ▶ The homography being computed with an arbitrary multiplicative factor, we write

$$\lambda H = K \begin{pmatrix} R_1 & R_2 & T \end{pmatrix}$$

- ▶ We rewrite:

$$\lambda K^{-1} H = \lambda \begin{pmatrix} K^{-1} H_1 & K^{-1} H_2 & K^{-1} H_3 \end{pmatrix} = \begin{pmatrix} R_1 & R_2 & T \end{pmatrix}$$

- ▶ 2 equations expressing orthonormality of R_1 and R_2 :

$$H_1^\top (K^{-\top} K^{-1}) H_1 = H_2^\top (K^{-\top} K^{-1}) H_2$$

$$H_1^\top (K^{-\top} K^{-1}) H_2 = 0$$

- ▶ With 3 views, we have 6 equations for the 5 parameters of $K^{-\top} K^{-1}$; then Cholesky decomposition.

The problem of geometric distortion

- ▶ At small or moderate focal length, we cannot ignore the geometric distortion due to lens curvature, especially away from image center.
- ▶ This is observable in the non-straightness of certain lines:

Photo: 5600×3700 pixels

Deviation of 30 pixels

- ▶ The classical model of distortion is radial polynomial:

$$\begin{pmatrix} x_d \\ y_d \end{pmatrix} - \begin{pmatrix} d_x \\ d_y \end{pmatrix} = (1 + a_1 r^2 + a_2 r^4 + \dots) \begin{pmatrix} x - d_x \\ y - d_y \end{pmatrix}$$

Estimation of geometric distortion

- ▶ If we integrate distortion coefficients as unknowns, there is no more closed formula estimating K .
- ▶ We have a non-linear minimization problem, which can be solved by an iterative method.
- ▶ To initialize the minimization, we assume no distortion ($a_1 = a_2 = 0$) and estimate K with the previous linear procedure.

Optimization techniques

Conclusion

Practical session/Home assignment

Linear least squares problem

- ▶ For example, when we have more than 4 point correspondences in homography estimation:

$$A_{m \times 8} h = B_m \quad m \geq 8$$

- ▶ In the case of an overdetermined linear system, we minimize

$$\epsilon(\mathbf{X}) = \|A\mathbf{X} - B\|^2 = \|f(\mathbf{X})\|^2$$

- ▶ The gradient of ϵ can be easily computed:

$$\nabla \epsilon(\mathbf{X}) = 2(A^\top A\mathbf{X} - A^\top B)$$

- ▶ The solution is obtained by equating the gradient to 0:

$$\mathbf{X} = (A^\top A)^{-1} A^\top B$$

- ▶ **Remark 1:** this is correct only if $A^\top A$ is invertible, that is A has full rank.
- ▶ **Remark 2:** if A is square, it is the standard solution $\mathbf{X} = A^{-1}B$
- ▶ **Remark 3:** $A^{(-1)} = (A^\top A)^{-1} A^\top$ is called the pseudo-inverse of A , because $A^{(-1)}A = I_n$.

Non-linear least squares problem

- ▶ We would like to solve as best we can $f(\mathbf{X}) = 0$ with f non-linear. We thus minimize

$$\epsilon(\mathbf{X}) = \|f(\mathbf{X})\|^2$$

- ▶ Let us compute the gradient of ϵ :

$$\nabla\epsilon(\mathbf{X}) = 2J^\top f(\mathbf{X}) \text{ with } J_{ij} = \frac{\partial f_i}{\partial x_j}$$

- ▶ Gradient descent: we iterate until convergence

$$\Delta\mathbf{X} = -\alpha J^\top f(\mathbf{X}), \alpha > 0$$

- ▶ When we are close to the minimum, a faster convergence is obtained by Newton's method:

$$\epsilon(\mathbf{X}_0) \sim \epsilon(\mathbf{X}) + \nabla\epsilon(\mathbf{X})^\top (\Delta\mathbf{X}) + (\Delta\mathbf{X})^\top (\nabla^2\epsilon)(\Delta\mathbf{X})$$

and minimum is for $\Delta\mathbf{X} = -(\nabla^2\epsilon)^{-1}\nabla\epsilon$

Levenberg-Marquardt algorithm

- ▶ This is a mix of gradient descent and quasi-Newton method (*quasi* since we do not compute explicitly the Hessian matrix, but approximate it).
- ▶ The gradient of ϵ is

$$\nabla\epsilon(\mathbf{X}) = 2J^T f(\mathbf{X})$$

so the Hessian matrix of ϵ is composed of sums of two terms:

1. Product of first derivatives of f .
 2. Product of f and second derivatives of f .
- ▶ The idea is to ignore the second terms, as they should be small when we are close to the minimum ($f \sim 0$). The Hessian is thus approximated by

$$H = 2J^T J$$

- ▶ Levenberg-Marquardt iteration:

$$\Delta\mathbf{X} = -(J^T J + \lambda I)^{-1} J^T f(\mathbf{X}), \lambda > 0$$

Levenberg-Marquardt algorithm

- ▶ Principle: gradient descent when we are far from the solution (λ large) and Newton's step when we are close (λ small).

1. Start from initial \mathbf{X} and $\lambda = 10^{-3}$.
2. Compute

$$\Delta \mathbf{X} = -(J^\top J + \lambda I)^{-1} J^\top f(\mathbf{X}), \lambda > 0$$

3. Compare $\epsilon(\mathbf{X} + \Delta \mathbf{X})$ and $\epsilon(\mathbf{X})$:
 - 3a If $\epsilon(\mathbf{X} + \Delta \mathbf{X}) \sim \epsilon(\mathbf{X})$, finish.
 - 3b If $\epsilon(\mathbf{X} + \Delta \mathbf{X}) < \epsilon(\mathbf{X})$,

$$\mathbf{X} \leftarrow \mathbf{X} + \Delta \mathbf{X} \quad \lambda \leftarrow \lambda/10$$

$$3c \text{ If } \epsilon(\mathbf{X} + \Delta \mathbf{X}) > \epsilon(\mathbf{X}), \lambda \leftarrow 10\lambda$$

4. Go to step 2.

Conclusion

Practical session/Home assignment

Conclusion

- ▶ Camera matrix K (3×3) depends only on internal parameters of the camera.
- ▶ Projection matrix P (3×4) depends on K and position/orientation.
- ▶ Homogeneous coordinates are convenient as they linearize the equations.
- ▶ A homography between two images arises when the observed scene is flat or the principal point is fixed.
- ▶ 4 or more correspondences are enough to estimate a homography (in general)

Conclusion

Practical session/Home assignment

Practical session: panorama construction

Objective: the user clicks 4 or more corresponding points in left and right images. After a right button click, the program computes the homography and shows the resulting panorama in a new window.

- ▶ Install Imagine++
(<http://imagine.enpc.fr/~monasse/Imagine++/>) on your machine.
- ▶ Let the user click the matching points.
- ▶ Build the linear system to solve $Ax = b$ and find x .
- ▶ Compute the bounding box of the panorama.
- ▶ Stitch the images: on overlapping area, take the average of colors at corresponding pixels in both images.

Useful Imagine++ types/functions: `Matrix`, `Vector`, `Image`, `anyGetMouse`, `linSolve`
